Managing Colic in Infants Pathway

Infant presenting with Colic (repeated episodes of excessive and inconsolable crying)

- Started in the first weeks of life
- The baby draws its knees up to its abdomen or arches its back when crying
- Crying most often occurs in the late afternoon or evening

Consider differential diagnosis if sudden onset

Also see Unsettled Baby Pathway

Take history and examine

- General health of the baby including growth
- Antenatal and perinatal history
- Onset and length of crying
- Nature of the stools
- Feeding and sleeping patterns
- Mother's diet if breastfeeding
- Family history of allergy (see Allergy Focused History form)
- Parent's response to the baby's crying
- Factors which lessen or worsen the crying
- Red flag symptoms which may suggest a more serious underlying issue

Treatable causes

- Hunger or thirst
- Too hot / too cold / too itchy
- Nappy rash
- Poor feeding technique
- Wind (ensure infant is upright if bottle feeding)
- Constipation if bottle fed
- Gastro-oesophageal reflux disease(GOR Pathway)
- Cow's milk protein allergy (<u>CMPA Pathway</u>)
- Transient lactose intolerance (Lactose Pathway)
- Parental depression or anxiety
- Mother's intake if breastfeeding: anecdotal, e.g. medication, high intake of caffeine/ alcohol/certain foods
- Rare serious causes (seizures, cerebral palsy, chromosomal abnormality)

Treatable causes and serious differentials excluded

Do not recommend

Simeticone (eg Infacol®),
Lactase drops (eg Colief®),
Probiotic supplements,
Herbal supplements,
Spinal manipulation or
Cranial osteopathy due to
lack of good quality
evidence and risk of harm

Management

- Reassure and acknowledge (do not ignore/dismiss concerns)
 colic usually improves by 3-4 months, resolving by 6 months
- Offer ongoing support and review
- Give parents safety netting leaflet
- Advise soothing strategies e.g. Holding baby through crying (although putting the baby somewhere safe is sometimes needed) or Gentle motion or White noise or Bathing in warm water
- Encourage parents to look after their own health and access appropriate support
- Encourage to continue breastfeeding wherever possible
- **Seek specialist advice** if parent unable to cope *or* infant is not thriving, or symptoms are severe or persist after 4 months

Managing Colic in Infants Pathway

Although infantile colic is considered to be a self-limiting and benign condition, it is often a frustrating problem for parents and caregivers. It is a frequent source of consultation with healthcare professionals and is associated with high levels of parental stress and anxiety.

Infantile colic is defined for clinical purposes as 'repeated episodes of excessive and inconsolable crying in an infant that otherwise appears to be healthy and thriving' [National Collaborating Centre for Primary Care, 2006]. Researchers use more specific definitions, often that of Wessel and colleagues: 'paroxysms of irritability, fussing or crying lasting for a total of three hours a day and occurring on more than three days in any one week for a period of three weeks in an infant who is otherwise healthy and well-fed' [Wessel et al, 1954].

Estimates of Prevalence

The worldwide prevalence of infantile colic is estimated to be about 20% [Vandenplas, 2015b]. A meta-analysis of 28 diary studies (n = 8690 infants) found the prevalence of colic was higher in the first 6 weeks of life (17–25%) compared with 11% by 8–9 weeks of age, and 0.6% by 10–12 weeks of age [Wolke, 2017]. One in six families with children with colic symptoms consult a healthcare professional [review: DTB, 2013]. Colic occurs equally in breastfed and bottle-fed infants, and equally in both sexes [Johnson, 2015; Vandenplas, 2015a]

The underlying cause of infantile colic is unknown.

Suggested underlying causes include:

- Parenting factors (for example overstimulating the baby and misinterpreting cries)
- Gastrointestinal causes (for example gastro-oesophageal reflux and constipation)
- Cow's milk protein allergy
- Transient intolerance to lactose (rare)

Others have suggested that colic is just the extreme end of normal crying, or that it is due to the baby's temperament (for example a baby with a sensitive temperament).

Possible complications

- o Parental stress, anxiety and/or depression
- Parental sleep deprivation
- Family tension and parent-infant attachment difficulties
- Premature cessation of breastfeeding, or premature introduction of solid foods
- o Increased risk of child maltreatment
